Statistics 641, Fall 2013 Homework #3 Solutions

1. Suppose that we have 20 patients, 10 per treatment group, and we observe the following survival times:

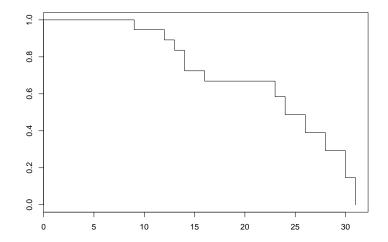

where the '+' indicates a censored observation.

For each of the following, please show your work (e.g., provide tables such as those on page 9 of lecture 5, or page 4 of lecture 6). You may use software to check your work.

(a) Compute and plot the Kaplan-Meier estimate of survival, $\widehat{S}(t)$ for the two groups combined.

Letting n_j be the number at risk at each time, d_j the number of events, and $\widehat{S}(t_j)$ estimate of the survivor function.

t_{j}	n_{j}	d_{j}	$1 - d_j/n_j$	$\widehat{S}(t_j)$	$d_j/n_j(n_j-d_j)$	$\sum d_j/n_j(n_j-d_j)$	$\operatorname{Var}\left(\widehat{S}(t)\right)$	95%CI
0	20	_	_	1.00	0	0	_	
9	19	1	18/19	0.947	1/19(19-1) = 0.002	9 0.0029	0.0026	(0.852, 1.000)
12	17	1	16/17	0.892	1/17(17-1) = 0.003	7 0.0066	0.0052	(0.760, 1.000)
13	16	1	15/16	0.836	1/16(16-1) = 0.004	0.0108	0.0075	(0.682, 1.000)
14	15	2	13/15	0.724	2/15(15-2) = 0.010	$3 \qquad 0.0210$	0.0110	(0.545, 0.963)
16	13	1	12/13	0.669	1/13(13-1) = 0.006	4 0.0274	0.0123	(0.483, 0.925)
23	8	1	7/8	0.585	1/8(8-1) = 0.017	9 0.0453	0.0155	(0.386, 0.888)
24	6	1	5/6	0.488	1/6(6-1) = 0.033	$3 \qquad 0.0786$	0.0187	(0.281, 0.845)
26	5	1	4/5	0.390	1/5(5-1) = 0.050	0.01286	0.0196	(0.193, 0.788)
28	4	1	3/4	0.293	1/4(4-1) = 0.083	0.2120	0.0181	(0.119, 0.721)
30	2	1	1/2	0.146	1/2(2-1) = 0.500	0.7120	0.0152	(0.028, 0.765)
31	1	1	0/1	0.000	$1/1(1-1) = \infty$	∞	∞	(0, -)

(b) Compute the variance of $\hat{S}(t)$ and a 95% confidence interval.

The variance of $\log(\widehat{S}(t))$ is $\sum_{j:t_j \leq t} \frac{d_j}{n_j(n_j - d_j)}$. The table above shows the terms $d_j/n_j(n_j - d_j)$.

 d_j) and the cumulative sum. By the delta-method, $v(t) = \text{Var}(\widehat{S}(t)) = \widehat{S}(t)^2 \text{Var}(\log(\widehat{S}(t)))$, shown in the next column. The 95%-CI is computed on the $\log(S(t))$ scale and converted back:

Upper limit =
$$\hat{S}(t)e^{1.96\sqrt{v(t)}}$$

Lower limit =
$$\hat{S}(t)e^{-1.96\sqrt{v(t)}}$$

(c) Assess equality of treatments using the log-rank test and the Gehan-Wilcoxon test.

	t_{j}	d_{j1}	n_{j1}	d_{j2}	n_{j2}	$n_{j1} + n_{j2}$ $(= w_j)$	$E[d_{j1}]$	$\operatorname{Var}(d_{j1})$
	9	0	9	1	10	19	$1 \times 9/19$	$1 \times 9 \times 10 \times 18/19^2 \times 18$
	12	0	8	1	9	17	$1 \times 8/17$	$1 \times 8 \times 9 \times 16/17^2 \times 16$
	13	0	8	1	8	16	$1 \times 8/16$	$1 \times 8 \times 8 \times 15/16^2 \times 15$
	14	0	8	2	7	14	$2 \times 8/15$	$2 \times 8 \times 7 \times 13/15^2 \times 14$
	16	0	8	1	5	13	$1 \times 8/13$	$1 \times 8 \times 5 \times 12/13^2 \times 12$
	23	1	6	0	2	8	$1 \times 6/8$	$1 \times 6 \times 2 \times 7/8^2 \times 7$
	24	1	5	0	1	6	$1 \times 5/6$	$1 \times 5 \times 1 \times 5/6^2 \times 5$
	26	1	4	0	1	5	$1 \times 4/5$	$1 \times 4 \times 1 \times 4/5^2 \times 4$
	28	1	3	0	1	4	$1 \times 3/4$	$1 \times 3 \times 1 \times 3/4^2 \times 3$
	30	1	2	0	0	2	$1 \times 2/2$	$1 \times 2 \times 0 \times 1/2^2 \times 1$
	31	1	1	0	0	1	$1 \times 1/1$	$1 \times 1 \times 0 \times 0/1^2 \times 0$
$\sum (\cdot)$		6					8.26	2.12
$\sum w_j(\cdot)$		26					70	394

We have for the unweighted log-rank:

$$\frac{(6-8.26)^2}{2.12} = 2.41$$

and for the Gehan-Wilcoxon-weighted log-rank:

$$\frac{(26-70)^2}{394} = 4.91$$

2. For the following use the data from the file data3.csv (available on-line at http://www.biostat.wisc.edu/~cook/641.homework.html). These data can be read into R using a command such as

```
data3 <- read.csv("data3.csv")</pre>
```

(or use a dataset name of your choosing).

The variables in the dataset are:

trt Treatment group (0/1)days Follow-up time in days status censoring/failure indicator (1=failure, 0=censored) sex Sex (1=Male, 2=Female) age Age at baseline in years

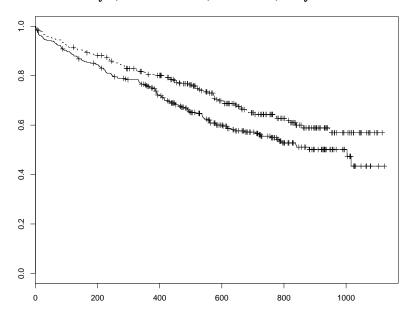

Let H_0 be the null hypothesis that there is no difference in survival by treatment.

First, read data into R:

> D <- read.csv("hw1.csv")</pre>

(a) Plot the Kaplan-Meier estimates of event-free survival by treatment group.

> plot(survfit(Surv(days,status)~trt, data=D), lty=1:2)

(b) Test H_0 using the Wald, score and likelihood ratio tests.

Fitting a Cox proportional hazards model,

> summary(coxph(Surv(days, status)~trt, data=D))
Call:
coxph(formula = Surv(days, status) ~ trt, data = D)

```
coef exp(coef) se(coef)
                                   z Pr(>|z|)
               0.7239
                        0.1335 - 2.42
trt -0.3231
                                       0.0155 *
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
    exp(coef) exp(-coef) lower .95 upper .95
       0.7239
                   1.381
                            0.5573
                                      0.9404
trt
Rsquare= 0.01
                (max possible= 0.99)
Likelihood ratio test= 5.98 on 1 df,
                                        p=0.01445
Wald test
                     = 5.86
                             on 1 df,
                                        p=0.01552
Score (logrank) test = 5.91 on 1 df,
                                        p=0.01507
```

the Wald statistic is Z = -2.42 (or the chi-square statistic is $5.86 = Z^2$, with 1 DF), and the likelihood ratio statistic is 5.98 (chi-square with 1 DF). The score test is the log-rank which yields a statistic of 5.91. All are close together and provide modest evidence of a difference between treatment groups.

(c) Provide a summary and 95% confidence interval for the observed treatment difference.

The hazard ratio estimate from the Cox-model above is HR = 0.7239 (0.5573, 0.9404)

(d) Test H_0 adjusted for age and sex using the Wald and likelihood ratio tests.

```
First fit the Cox-model including age and sex effects:
> summary(coxph(Surv(days,status)~trt + age + sex, data=D))
Call:
coxph(formula = Surv(days, status) ~ trt + age + sex, data = D)
 n = 622
         coef exp(coef)
                         se(coef)
                                       z Pr(>|z|)
trt -0.337584 0.713492
                         0.133585 -2.527 0.01150 *
age 0.021732 1.021970
                         0.007538 2.883

sex
                 (max possible= 0.99 )
Rsquare= 0.023
Likelihood ratio test= 14.54
                              on 3 df,
                                         p=0.002257
Wald test
                     = 14.23
                              on 3 df,
                                         p=0.002613
Score (logrank) test = 14.31
                              on 3 df,
                                         p=0.002512
```

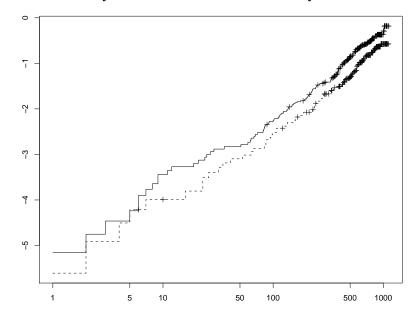

The Z statistic from the Wald test is Z = -2.527. To derive the likelihood ratio test we can simply take the difference between the likelihood ratio statistics for the models

with and without treatment, or we can use the anova function:

```
> anova(coxph(Surv(days,status)~ age + sex, data=D),
+    coxph(Surv(days,status)~trt + age + sex, data=D), test="Chis")
Analysis of Deviance Table
Cox model: response is Surv(days, status)
Model 1: ~ age + sex
Model 2: ~ trt + age + sex
    loglik Chisq Df P(>|Chi|)
1 -1426.1
2 -1422.8 6.5277 1 0.01062 *
---
Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
The adjusted likelihood-ratio statistic is 6.5277.
```

(e) Assess whether the proportional hazards assumption for the treatment difference is reasonable.

```
> plot(survfit(Surv(days,status)~trt, data=D), lty=1:2, fun="cloglog")
```

These curves remain roughly the same distance apart for the portion where they are most stable—there is no evidence from the plot that the PH assumption does not hold. Using the cox.zph function for the unadjusted and adjusted models, we have

```
sex    0.0154 0.05721 0.811
GLOBAL    NA 0.27726 0.964

Neither suggest that there is evidence the PH assumption fails.
In SAS, the PH test can be run as follows:
proc import datafile="hw1.csv" dbms=csv out=hw1;
proc phreg data = hw1;
    model days*status(0) = trt daystrt;
    daystrt = trt*log(days);
```

with selected output:

Analysis of Maximum Likelihood Estimates

Variable	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio
trt	_	-0.43342	0.51810	0.6998	0.4028	0.648
daystrt		0.02098	0.09502	0.0488	0.8252	1.021

The Wald chi-square statistic is 0.0488 (p=.82), so, again, there is no evidence that the PH assumption fails. (Note that the estimate for treatment in the above is not meaningful because of the presence of the time-treatment interaction term.)
